

ADJUSTABLE SOFT NECK BRACE

ABSTRACT OF THE DISCLOSURE

An adjustable neck brace system with a brace body,
5 elongate inserts, and engaging members. The brace body is
made of flexible material, has two side edges and a top and
bottom edge, and has a plurality of tunnels formed
therethrough, with each tunnel having a first, smaller
internal diameter when in an unstretched condition. The
10 inserts are received in the tunnels. The engaging members are
affixable in the vicinity of the side edges of the brace body
and are used for retaining the neck brace around a wearer's
neck. By selecting inserts that have an outer diameter that
is larger than the first, smaller internal diameter of the
15 brace body in its unstretched condition, the tunnels will be
stretched, which also stretches the brace body, thereby
lengthening the distance between the bottom edge and top edge
of the brace body.
